Step by Step Implementation: 3D Convolutional Neural Network in Keras

Michael Chan

In this article, we will be briefly explaining what a 3d CNN is, and how it is different from a generic 2d CNN. Then we will teach you step by step how to implement your own 3D Convolutional Neural Network using Keras.

1] What is a 3D Convolutional Neural Network?

A 3d CNN remains regardless of what we say a CNN that is very much similar to 2d CNN. Except that it differs in these following points (non-exhaustive listing):

3d Convolution Layers

Originally a 2d Convolution Layer is an entry per entry multiplication between the input and the different filters, where filters and inputs are 2d matrices. (fig.1)

2d Convolution

fig.1 (copyrighted: own)

In a 3d Convolution Layer, the same operations are used. We do these operations on multiple pairs of 2d matrices. (fig.2)

3d Convolution

3	2	1	3
0	7	3	3
3	9	3	4
2	3	8	3

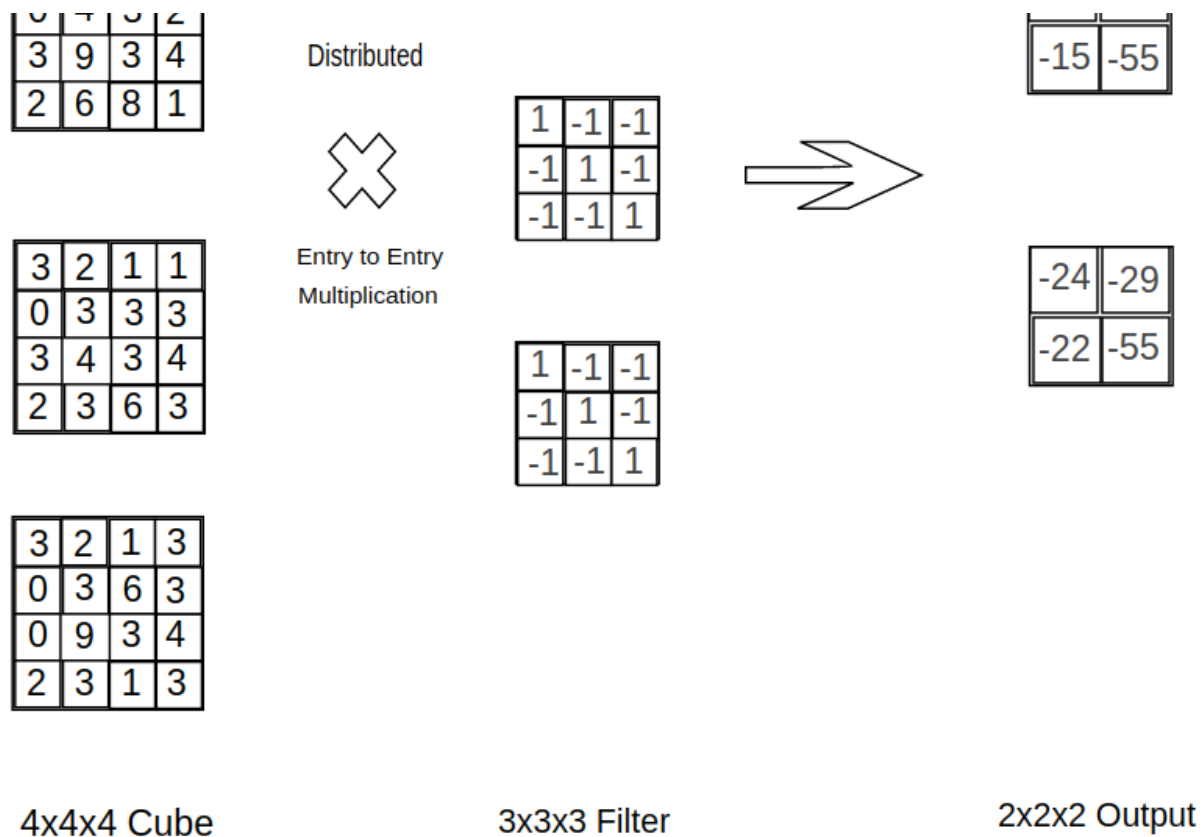

fig.2 (copyrighted: own)

Padding options and slides step options work the same way.

3d MaxPool Layers

2d Maxpool Layers (2x2 filter) is about taking the maximum element of a small 2x2 square that we delimitate from the input. (fig.3)

2d MaxPool

Now in a 3d Maxpool (2x2x2), we look for the maximum element in a width 2 cube. This cube represents the space delimited by the 2x2x2 zone from the input. (fig.4)

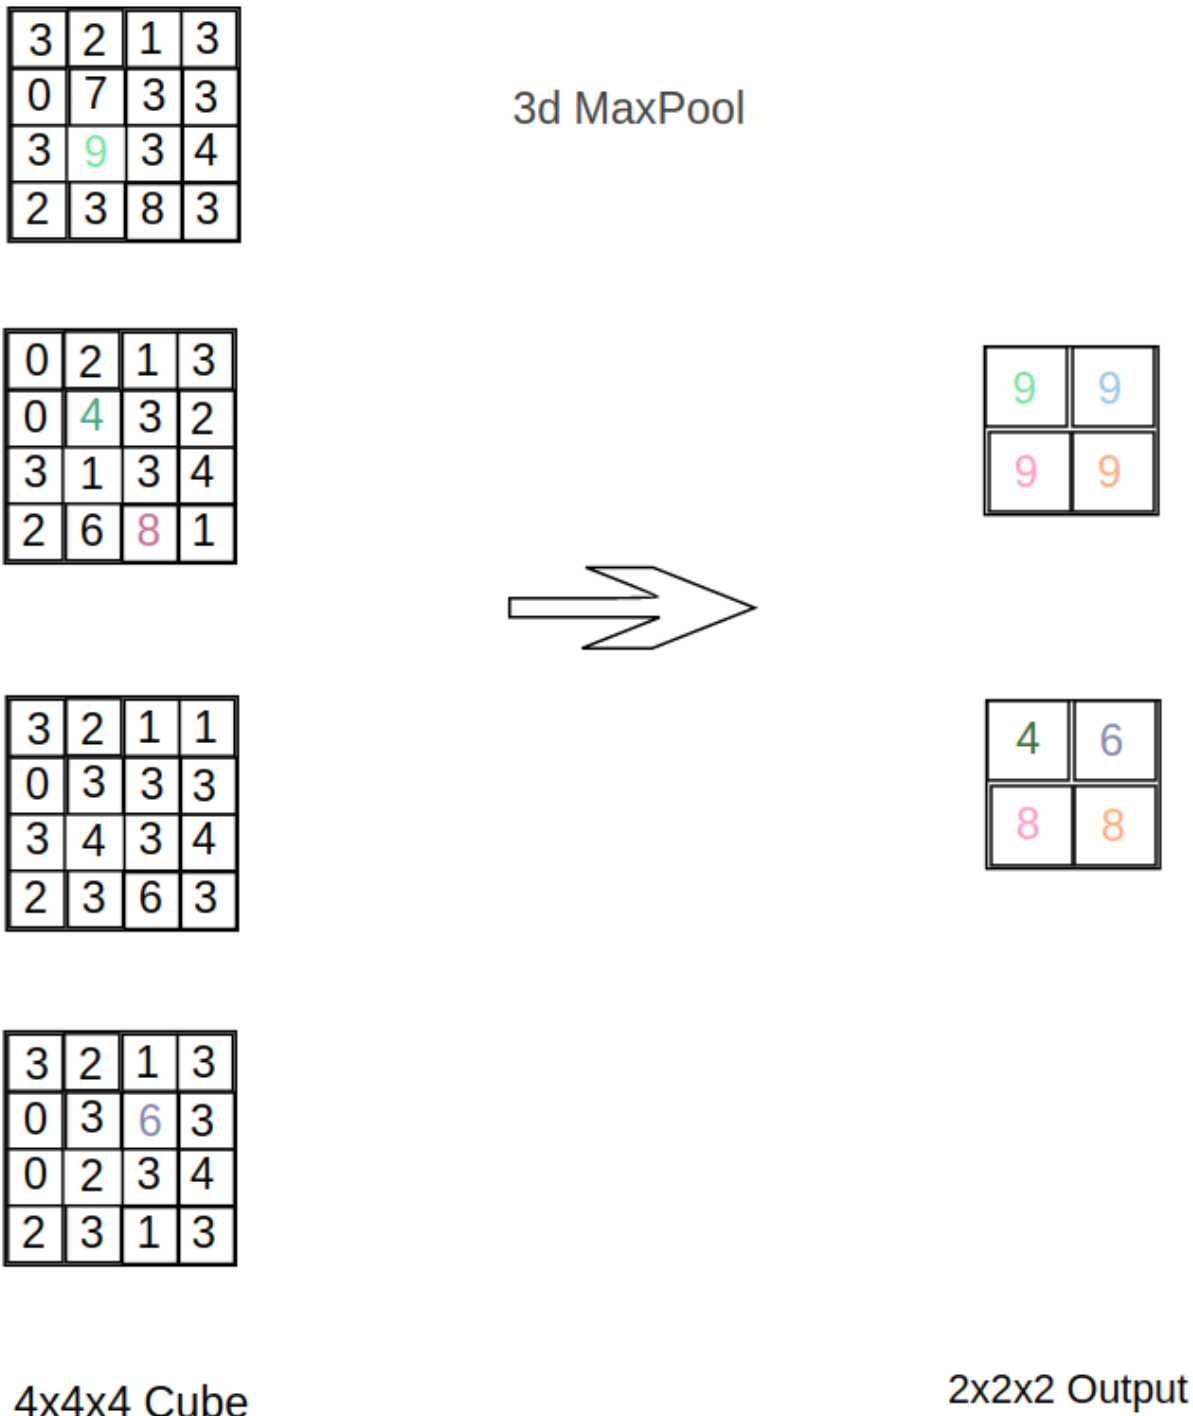

fig.4(copyrighted: own)

Note that the number of operations (compared to 2d CNN layers) is multiplied by the size of the filters used (regardless of the layer being Maxpool or Convolution) and also

So how does a data point for a 3d CNN look like?

One way to picture it is by using the following image (fig.5):

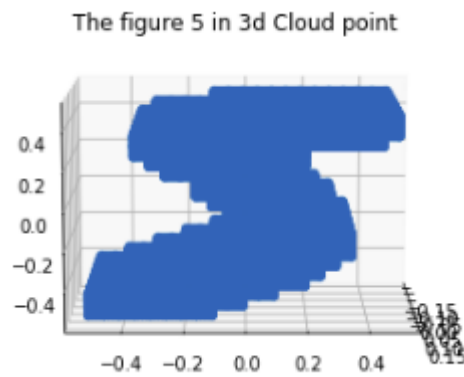

fig.5 (copyrighted: own)

Other existing datasets that you can use for your CNN are:

- RGB-D devices: [Google Tango](#), [Microsoft Kinect](#), etc.
- [Lidar](#)
- [3D reconstruction from multiple images](#)

3] Preprocessing and Implementations

You can try for yourself the code on this dataset from [Kaggle](#) that we are using.

The required libraries to import are as follows:

```
1  import os
2  os.environ["CUDA_DEVICE_ORDER"] = "PCI_BUS_ID"   #if like me you do not have a lot of n
3  os.environ["CUDA_VISIBLE_DEVICES"] = "" #then these two lines force keras to use your C
4  import keras
5  from keras.models import Sequential
6  from keras.layers import Dense, Flatten, Conv3D, MaxPooling3D, Dropout, BatchNormalizat
7  from keras.utils import to_categorical
8  import numpy as np
9  import matplotlib.pyplot as plt
10 import h5py
```

To begin with, since the dataset is a bit specific, we use the following to helper functions to process them before giving them to the network.

```
1 def array_to_color(array, cmap="Oranges"):
2     s_m = plt.cm.ScalarMappable(cmap=cmap)
3     return s_m.to_rgba(array)[:,-1]
4
5
6 def rgb_data_transform(data):
7     data_t = []
8     for i in range(data.shape[0]):
9         data_t.append(array_to_color(data[i]).reshape(16, 16, 16, 3))
10    return np.asarray(data_t, dtype=np.float32)
```

Plus, the dataset is stored as h5 file, so to extract the actual data points, we are required to read from h5 file, and use the to_categorical function to transform it into vectors. In this step, we also prepare for cross-validation.

```
1 with h5py.File("../full_dataset_vectors.h5", "r") as hf:
2
3     # Split the data into training/test features/targets
4     X_train = hf["X_train"][:]
5     targets_train = hf["y_train"][:]
6     X_test = hf["X_test"][:]
7     targets_test = hf["y_test"][:]
```

```
11
12     # Reshape data into 3D format
13     X_train = rgb_data_transform(X_train)
14     X_test = rgb_data_transform(X_test)
15
16     # Convert target vectors to categorical targets
17     targets_train = to_categorical(targets_train).astype(np.integer)
18     targets_test = to_categorical(targets_test).astype(np.integer)
19
```

Finally, the model and the syntax for 3d CNN are as follows: (the architecture was picked without much refining since that is not the point of this article)

```
1  # Create the model
2  model = Sequential()
3  model.add(Conv3D(32, kernel_size=(3, 3, 3), activation='relu', kernel_initializer='he_u
4  model.add(MaxPooling3D(pool_size=(2, 2, 2)))
5  model.add(BatchNormalization(center=True, scale=True))
6  model.add(Dropout(0.5))
7  model.add(Conv3D(64, kernel_size=(3, 3, 3), activation='relu', kernel_initializer='he_u
8  model.add(MaxPooling3D(pool_size=(2, 2, 2)))
9  model.add(BatchNormalization(center=True, scale=True))
10 model.add(Dropout(0.5))
11 model.add(Flatten())
12 model.add(Dense(256, activation='relu', kernel_initializer='he_uniform'))
```

×

```
16 # Compile the model
17 model.compile(loss='categorical_crossentropy',
18               optimizer=keras.optimizers.Adam(lr=0.001),
19               metrics=['accuracy'])
20 model.summary()
21 # Fit data to model
22 history = model.fit(X_train, targets_train,
23                   batch_size=128,
24                   epochs=40,
25                   verbose=1,
26                   validation_split=0.3)
```

Note that the numbers of parameters will be a lot higher for the same number of layers compared to 2d CNN.

For your information, after a small sample training, we got the following accuracies and losses. (fig.6)

Model performance for 3D MNIST Keras Conv3D example

4] But then a 3d? What for?

There happens to have many applications for a 3d CNN that are for instance:

- IRM data processing and therefore the inference
- self-driving
- Distance estimation

Alright, that's pretty much all. I hope you will try this technology out!

. . .
